

***Trirhithrum crescentis* Hancock**

Trirhithrum crescentis Hancock, 1984: 294.

Wing length=3.2 mm.

Male

Head: Arista plumose. Two pairs of frontal setae. Face dark (may be discoloured).

Thorax: Postpronotal lobe pale with a dark spot. Scutum with an ill-defined whitish microtrichose covering. Scutellum disk dark; margin not marked with pale spots baso-laterally or adjacent to apical setae. Anepisternum largely dark; dorsal edge narrowly pale; one seta. Anatergite without a silvery spot.

Wing: Pattern distinct. Subbasal and discal crossbands fused posterior to Rs and cell c extensively hyaline; discal crossband distally aligned to apex of pterostigma and R-M crossvein within discal crossband. Subapical crossband joined to discal crossband; base narrow, largely or entirely confined to cell r_{4+5} . Posterior apical crossband complete, extending from vein C to wing margin. Anal lobe coloured, but with a hyaline indentation (ending before vein A_1+Cu_2). No bulla.

Legs: Femora pale.

Abdomen: With distinct grey microtrichose bands on terga II and IV.

Female

Unknown; expected to be similar to male, but likely to have dark femora.

(description after White et al., 2003)
